# Abstract

Program #1363

<u>Purpose</u>: To evaluate the histopathology of the retina in donor eyes from a patient with Stargardt disease caused by *ABCA4* mutations. <u>Methods</u>: Eyes from a 66 year-old female were fixed in 4% paraformaldehyde and 0.5% glutaraldehyde in PBS within 18 hours postmortem. Globes were

and 0.5% glutaraldehyde in PBS within 18 hours postmortem. Globes were evaluated with macroscopic, SLO and OCT imaging. Perfloves and peripheral regions were processed for electron microscopy and immunocytochemistry Three age-similar normal eyes were used as controls. Genetic testing was done by both SSCP and direct sequencing of the ABCA4 gene.

Results: Donor ABCA4 gene analysis revealed three heterozygous mutations exon 42, namey Giyt991510. Heterozygous IVS46+2 C>G mutation in exon 46. All imgging modalities showed peripheral areas with few bone FPE atrophy as visualized by SLO autofluorescence. The fovea and optic nerve were dearly identified in OCT. Histology showed a degenerated retina with only a few disorganized photoreceptors and the absence of RPE in the perifovea. The macula was severely degenerated, with little evidence of any retinal cell layer including the RPE. In contrast, stratified nuclear layers were observed in the retinal periphery. In the periphery, the RPE was present and linkker than normal, but lacked melanin jigment. Cones were present and linkker than normal, but lacked melanin jigment. Cones were present and linkker than normal, but lacked melanin jigment. Cones were present and linkker dheaded modore neurons were sparse in the perifovea but were more abundant in the periphery. No labeling with asy of the diseled with GFAP was increased in the perifovea was gipficiently reduced in areas where the RPE remained. In the periphery, the RPE was where the RPE remained. In the periphery, the RPE was tissue. Autofluorescent material periphery. No labeling with any of the disabeled with GFAP was increased in the perifovea was significantly reduced in areas where the RPE remained. In the periphery, the RPE was hypertophied and the autofluorescent material interse.

Significant accumulation of autofluorescent material in the BPE in the perithem of the Stargard form retime, Revenential ve effluorescence protomicrographs of cryosections obtained from the Stargard donor (B, E) and matched control (A, C, D). Sections were observed using the green channel (FIC) (Bne: exclation 485mv emission STarm). Hypertrophic RPE from the Stargard donor retinal displayed applications in the stargard stargard stargard donor retinal displayed applicative protocols and the stargard donor retinal displayed applicative donor stargard stargard stargard donor retinal displayed applicative donor stargard stargard stargard donor retinal displayed applicative donor stargard stargard donor retinal displayed applicative donor stargard stargard donor retinal displayed applicative donor stargard displayed and stargard donor retinal displayed applicative donor starger (D). Autofluorescence was also observed in the photoresceptor inner and outer segments detached from the top of the RPE (C, Ph), due to the presence of quarkinghyle in the basins outdoor. Barr 4-40pm.

# Introduction

Stargardt disease is an autosomal-recessive macular disease with estimated frequency between 1 in 8,000 and 1 in 10,000 (Biacharski, 1988). Over 600 disease-causing mutations in the ABCA4 gene have been reported, with the three most common mutations accounting for less than 10% of the disease phenotypes (Allikmets et al., 2007).

Stargardt disease is characterized by excessive accumulation of lipoluscin in the RPE (Dideciyan et al., 2004). The general course of the disease is a slow progressive loss of central vision due to transport profile haracteristic activity of the transport of the transport of altransport registration relinat through the dise membrane. ABCA4 protein dystanction determines accumulation of altransa relinat through the dise membrane. ABCA4 protein dystanction determines accumulation of altransa relinat through the dise membrane. ABCA4 protein dystanction determines accumulation of altransa relinat through the dise membrane. ABCA4 protein dystanction determines accumulation of altransa relinat through the dise membrane. ABCA4 proteins distances as protein by RPE. Altrans relination is altransa relination altransa RPE and photocopions taking (Mathemes et al., 2001).

# (1) Fundus Macrography of Donor Eyes

Fundus image of eyes from a Stargardt disease (SD) donor due to compound heterozygous <u>ABCA4 mutations</u>. Fundus photograph of both the right (A) and left (B) eyes of a Stargardt disease patient at age 55, when last seen for examination showing a normal-appearing optic disc and RPE atrophy with hyperiginented areas adjacent to the forea (arrowhead). Images of 68 year-old donor eyes (C, D) also display RPE atrophy (arrows) in the periforea.

# CONTROL BARGARDT DONOR

(7) Immunocytochemistry

Increased presence of Müller cells which have undergone reactive gliosis in the says of a Stargard denor, Representative photomicographs of crystections oblande from the Stargard donor, and age-animatic control. Sections were labeled with hatdockes were labeled with TO-FPO-3 (hate). While blue core opsin is restricted in the outer segments of the cores in the control (A) is it nor in the Stargard donor refers in the periphery (B). The Muller cells had undergone reactive gliosis throughout the refers and their hypertropic processes were GPAP positive in the of the Stargard donor (B) but not in the control refinal (A). A decrease in the presence of blue cores was detected in the stargard donor in the positive, B) when compared to its control periphers (C). The stargard donor in the peripher control stargard donor refers (C). CCL-angrighton cell layer. RL+interrefinal mudera layer, CPL-coder peoplem layer.

# Conclusions

# The retina of a Stargardt disease donor displays:

 In the periphery all the retinal layers were present, with lower degree of degeneration in the OPL. The RPE was increased from its normal thickness and displayed lack of pigment;

- The perifovea displayed absence of the outer nuclear layer and photoreceptors. The nuclei in the inner nuclear layer were significantly decreased. Although the RPE was mostly absent from this area, Bruch 3 membrane was still present;
- The macula revealed a highly degenerated retina with little evidence of stratified nuclear layers and the presence of a giant lipophilic drop in the choroid;
   Presence of stubby, disorganized cones in the periphery and absence of cones in the peripovea;
- Presence of rods in the periphery and absent in the perifoves;
   Increased distribution of calbindin positive cells in the periphery and decreased in the peripherya.
- Increased Müller cells which have undergone reactive gliosis both in the periphery and perforea;
- peripriery and perifoves; In the periphery, blue cone opsin is distributed in the inner and outer segments, but blue cones were significantly decreased in the perifoves;
- Significant increase of autofluorescent material in the RPE in the periphery but decrease of autofluorescent material in the RPE in the periphery.

# Abstract

#1364

Purpose: To compare the histopathology in donor eyes from patients with autosomal int retinitis pigmentosa (adRP) caused by Pro23His, Pro347Thr and Pro347Leu

Methods: Eyes were obtained from 72, 80 and 83 year-old donors and fixed in 4% Metrodos: Eyes were obtained from 72, ou and so year-old donors and nixed in 4% paraformaldehyde and 0.5% glutaraldehyde in PBS within 8 to 17.5 hours postmortem. Globes were evaluated with macroscopic, SLO and OCT imaging. Macula and peripheral regions were processed for microscopy and immunocytochemisty. Three age-matched normal eves were used as controls. DNA was obtained from blood and

buccal samples of the donor and family members. Direct genomic sequencing of the entire rhodopsin coding region and flanking intronic sequences was performed. Results: DNA analysis of the donors and affected family members revealed rhodopsin Pro23His, Pro347Thr and Pro347Leu mutations. Histopathological findings in the retina of the donor carrying a Pro23His rhodopsin mutation were reported previously and are compared here to donors carrying the Pro347Thr and Pro347Leu mutations. The area irrounding the optic nerve showed evidence of RPE atrophy as choroidal vasculature surrounding the optic nerve showed evidence of RPF2 arophy as choroidal vasculature could be visualized in the Pro23His and Pro347Thr eyes. A prominent inner nuclear layer was present in the perifoveal region in the Pro23His eye. In addition, the RPE was reduced from normal thickness in the macula in the Pro23His eye while it was was reduced non-normal increases in the indicate in the Pro23rise eye while it was discontinuous in the Pro347Thr and Pro347Leu eye in the macular region. Coness labeled with opsin and arrestin antibodies were present in the macula, but were mostly absent from the periphery in the Pro23His eye. Few cones were present in the macune peripher in the Pro23His eye. Pro347Thr and Pro347Leu eyes. A few highly disorganized, rhodopsin labeled rods were detected in the macula but were absent in the periphery of the Pro34His eye. The relinas of the Pro347Thr and Pro347Leu eyes showed almost complete absence of nodopsin labeled rods in both the perifovea and periphery.

<u>Conclusions:</u> The histopathology of the retina in patients with Pro23His rhodopsin mutation displayed highly degenerate peripheral retina and preservation of some cone and rod photoreceptors in the macula. The retina in patients with Pro347Thr and Pro347Leu rhodopsin mutations displayed near-complete loss of rods and the sence of few cones in the macula.

# Conclusions

The retinas of adRP donors carrying rhodopsin mutations display:

esearch to Prevent Bi

highly degenerate retina with disorganization of the lamina and cellular layers and gliosis in peripheral areas of all rhodopsin mutations;

prominent inner nuclear layer in the perifovea in the donor carrying Pro23His mutation;

RPE reduction from normal thickness in the perifovea in the donor carrying Pro23His mutation;

severely atrophic retina and discontinuous RPE in the perifovea of donor carrying Pro347Leu mutation;

prominent inner nuclear layer with the presence of patchy disorganized cones in the perifovea in the donor carrying the Pro347Thr mutation;

near-absence of rods both in the periphery and in the perifovea in all adRP retinas:

 absence of cones in the periphery of all adRP donors carrving rhodopsin mutations

presence of disorganized cones in the perifovea of donors carrying both the Pro23His and Pro347Thr

complete absence of cones in the perifovea of donor carrying Pro347Leu mutation.

# Rhodopsin Gene Mutations

ately 15 - 35% of RP cases are autosomal dominant (adRP). According to RetNet, 23 different genes have been associated with adRP. The most common gene to cause adRP

the rhodopsin (RHO) gene—accounting for 20-30% of patients. The most common mutation in RHO is the Pro23His mutation, which is found in about one third of patients. A few previous studies reported analysis of the relinal histology of eyes with the Pro23His mutation. Those studies all showed variable histological findings in the relina with a final common pathway leading to photoreceptor cell death (Koll & Gouras, 1974; To et with a final course, 1974; To et an analysis of the state of the stat

with a final common pathway leading to photoreceptor cetil death (Kolb & Gouras, 1974, 1984) al. 2002; Tot et al. 2004). Pro347 is a mutation hotspot in *RHO* with at teast 4 mutations reported. It was previously reported that a human eye carrying the Pro347Leu mutation displayed focal, cone sparing (Marc et al., 2007). In addition, analysis of patients carrying his mutation showed that they displayed come-mediated vision, extractional relative bayed loss of OML, hickening of the inner refina, and demelanization of RPE (Aleman et al., 2008). Pro347Thr has also been nerviewish monthering et al., 2007). eviously reported in patients (Dryja et al., 2000).

According to Nathans and Hogness (1984), the 348-amino acid RHO protein has 7 transmembrane domains, with a luminal N terminus and a cytoplasmic C terminus. The mic face of rhodopsin is made up of 3 loops. The C-terminal tail contains the catalytic cytoptamic face of modopsin is made up of 3 loops. The C-terminal tail contains the catalytic site that promotes GTP-GDP exchange by transducin and several putche sites for Inju-dependent phosphorylation by motopsin kinase. Rhodopsin also has 2 sites for N-sylocarylation, and guided by the catalogue of the catalogue and the site of the Rhodopsin is essential for photoreceptor morphogenesis. Here we analyzed and reported for the fast lime the distribution of photoreceptors and other relatal cells in adults carrying point Pro37Lau) region of the rod outer segments (see arrows in scheme below).

# Abstract

Purpose: To compare the histopathology in donor eyes from patients with Best disease (BD) caused p.Asn296His and p.Ile201Thr VMD2 mutations.

Program # 6332

Methods: Eyes were obtained from 85 year-old (donor 1, female), and 65 year-old (donor 2, male) postmortem donors, and were fixed within 25 hrs postmortem. Globes were evaluated with nacroscopic, SLO and OCT imaging. Perifoveal and peripheral retinal regions were processed for electron microscopy and immunocytochemistry using cell-specific antibodies. Four age-similar normal eyes were used as controls. DNA was obtained from donor blood samples. Sequence analysis of the entire VMD2 coding region was performed.

Results: DNA analysis of donor 1 detected a p.Asn296His VMD2 mutation. DNA analysis of donor detected a p.Ile201Thr VMD2 mutation. Fundus examination showed that donor 1 displayed a macular lesion with considerable scarring while donor 2 displayed close to normal macular morphology. Imaging modalities indicated considerable retinal atrophy in the perifoyeal region of donor 1. In each BD donor, histology showed a distinct ganglion cell layer (GCL), inner nuclear layer (INL), outer nuclear layer (ONL), RPE and choriocapillaris (CC) in the periphery. In addition, donor 1 displayed edema of the interphotoreceptor matrix. Prominent GCL and INL were evident in the perifoveal region of donor 1. In addition, an extensive fibrovascular scar was present between Bruch's membrane and the retina; this area also displayed patchy thin RPE with no photoreceptors. In contrast, the perifoveal region of donor 2 had distinct GCL, INL, ONL and robust RPE and CC. Cells labeled with cone opsin and arrestin antibodies were evident in the macula, but mostly absent in the reting adjacent to the fibrovascular scar of donor 1. In the periphery of both BD donors, cells labeled with cone-specific antibodies were present. Cells labeled with rhodopsin were detected in the perifoveal region but not in the fibrovascular scar area of donor 1. Cells labeled with rhodopsin antibody were present in the periphery of both donors. Autofluorescent material in the perifoveal region was significantly reduced in areas where the RPE was still present in donor 1. Conclusions: The histopathology of the retina from an individual with a VMD2 p.Asn296His mutation displayed a highly degenerated perifoveal retina. The retina in the individual with a p.Ile201Thr VMD2 mutation displayed normal perifoveal morphology with preservation of cones and rods in the periphery. Support: The Foundation Fighting Blindness, Research to Prevent Blindness, Wolf Family Foundation, National Eve Institute, and Llura and Gordon Gund Foundation

# Fundus & SLO Images of Donor Eyes

Figure 1. Ex vivo fundus imaging of donors and an age-similar control eye. Macros r fundus and SLO image rer LZ vivo innovi imaging of outors and an agestimar control eye, watcoscopic timutas and sLO images collected using an AxioCam MRCS camera with vido zoom lens (Zeiss) and a model HRA2 SLO (Heidelberg neering), respectively. All eyes showed areas of artifact (detached retina; d) due to fixation and processing. All maging modalities indicated that the control eye (A, D, F) is free of retinal pathology. In contrast, all images from lonor 1 (B,E,G) showed a macular lesion that was more noticeable by visible light fundus macroscopy (B) than either RDF-SLO (E) or AF-SLO (G). AF-SLO (G) of donor 1 showed a bright, autofluorescent fundus which lacked typical letail (absence of a macula lutea) and appeared more homogeneous than the control eye (F). Donor 2 (C) was absent o inv obvious retinal lesions but did have substantial fixation artifact (folds). No SLO or OCT images are available for or 2. Scale bar - 2mm

# **OCT Images of Donor Eyes**

Figure 2. Ex Vivo OCT imaging of the donor (C,D) and an age-similar control eve (A,B). Spectral Domain-OCT images were collected using the Model SDOIS system (Bioptigen, Inc.) with ~7x7mm field of view. The control eyes had intact retinas that (1) were still adherent and congruent with the RPE-choroid complex and showed evidence of a photoreceptor layer (B - dark space above arrows). In contrast, the B-scan image from the donor eve (D) lacked a well-defined photoreceptor layer and exhibited a hyper-reflective RPE (arrows) compared to the control eye. Regions of minor retinal detachment (d) and elevated retina (^) were also observed due to fixation and processing. Dashed lines in *en face* imag indicates B-scan location, optic nerve (ON), B-scan scale bar is 0.5mm. also obse

Figure 3. Degeneration in the retinas of donor eyes with VMD2 mutations. Representative photomicrographs from toluidine blue stained plastic sections (1µm) of both the donor retinas and an age-similar control are shown for comparison. Morphology of control retina in the periphery (A) and perifovea (D) displayed typical characteristics including structural lamina consisting of retinal cells. In the periphery both donor 1 (B) and donor 2 (C) displayed a distinct ganglion cell laver (GCL), inner nuclear laver (INL), outer nuclear lave (ONL), RPE and choriocapillaris (CC). Donor 1 also displayed edema of the nterphotoreceptor matrix (B, arrow). Both donor 1 and 2 displayed RPE Interprotection frains (fr, arrow). Door boor of an 2 subject of a thinning but door 2 also displayed the presence of few drusen (C°, asterisks) under the RPE in the periphery. In the perfoveal region of donor 1 prominent GCL and INL were vident. In addition, an extensive fibrovascular scar was present between Bruch's membrane and the retina (E, star); this area also displayed patchy thin RPE (arrowheads) with no photoreceptors. In contrast, the uspayed patch yun ret (entwines) with in photocecplos. In terms of the perfove region of donor 2 had distinct GCL, INL, ONL and robust hin RPE (F', arrowheads) and CC. GCL= ganglion cell layer, INL= inner nuclear layer; ONL= outer nuclear layer; SoP photoreceptor outer segments; RPE= retinal pigment epithelium. Bars =50µm.

Figure 4. Significant decrease in rods in the perifovea of donor eyes with an Asn296His VMD2 mutation. Representative photomicrographs of cryosections collected from the age-similar control and the donors. Sections are shown labeled with antibodies specific to rhodonsin (Alexa488 green) while cell nuclei were with antioodies specific to mooopsin (Alexa+88, green) while cell nuclei were labeled with TO-PRO-3 (blue). In the control retina rhodopsin was restricted to the rods outer segment both in the periphery (A) and periforcea (D). In the periphery of the donor 1 (B) rhodopsin was also distributed throughout the whole photoreceptor cells (arrows). In the periphery of donor 2 (C) rhodopsin labeling was decreased but still restricted to the outer segments. In the perifove of donor 1 (E) several very disorganized rhodopsin-labeled cells were detected opposed to the RPE cells and within the few photoreceptor nuclei still present (arrows). Bruch's membrane indicated by hashed white line. GCL= ganglion cell layer; INL= inner nuclear layer; ONL= outer nuclear layer. Bar = 40µm.

Figure 5. Significant decrease in cones in the perifovea of donor eves with an Asn296His VMD2 mutation. Representative photomicrographs of cryosections obtained from the donors and an age-similar control. Sections were labeled with antibodies specific to red/green cone opsin (Alexa488, green) and GFAP (Alexa594, red) while cell nuclei have been labeled with TO-PRO-3 (blue). In the control retina red/green cone opsin distribution was restricted to the cone outer segments both in (teg perior tone dynamisminianiam was resurced to use conclusively and the periphery (A) and perifiveral (D). In the periphery (A) and perifiveral (D). In the periphery of both donors 1 (B) and 2 (C) cells labeled with red/green cone opsin were present but red/green cone opsin was also distributed to the photoreceptor inner segments and synapses (B, C, arrows). In contrast, cells labeled with red/green cone opsin antibodies were mostly absent in the retina adjacent to the fibrovascular scar of donor 1 (E). The Muller cells had undergone reactive gliosis throughout the retina and their hypertrophic processes were GFAP positive in the periphery of donor 2 (C) and perifovea of donor 1 (E) when compared to the control retina (A. D). GCL= ganglion cell laver: INL= inner nuclear layer; ONL= outer nuclear layer. Bar = 40µm

# Immunocytochemistry of Donor Eyes

Figure 6. Changes in the distribution of monocarboxylate transporter 3 (MCT3) in the RPE of donor eves with VMD2 mutations. Representative photomicrographs of cryosections obtained from the donors and an age-similar control. Sections were labeled with antibodies specific to MCT3 (Alcus488, green) while cell nuclei have been labeled with O-PRO-5 (blue). In the control retina MCT3 distribution was restricted to the basolateral domain of the RPE both in the periphery (A) and perifovea (D). In the periphery of donor 1 (B) MCT3 distribution was not altered while donor 2 displayed significant decrease in the expression of MCT3 in RPE cells (C). In contrast, in the perifovea of donor 1 (E) MCT3 was distributed in both the apical and basolateral membranes RPE cells (arrows)

authors thank Dr. Nancy J. Philp, Thomas Jefferson Univ., Philadelphia, PA, for providing the MCT3 antibody.

Figure 7. Significantly decreased autofluorescent material in the RPE of VMD2 donor eyes. Representative epifluorescence photomicrographs of cryosections obtained from the donors and an age-similar control. Sections were observed using the green channel (FITC filter: excitation 490nm/ sion 519nm) and red (TRITC filter: excitation 550/emission 570nm). Autofluorescence was overlaid on differential interference contrast (DIC) images. Autofluorescent granules are present in the control RPE both in the periphery (A) and perifovea (D). In the periphery, the RPE from both donor 1 (B) and 2 (C) displayed significantly decreased autofluorescent granules when compared to the control RPE (A). In addition, RPE from the donor 1 (E) displayed significantly decreased autofluorescent granules in the perifovea when compared to the control RPE. Bar = 40µm.

# Conclusions

The retina of Donor 1 (Asn29His VMD2 mutation) showed:

- A reacular lesion by Fundus' SLO imaging Periphery: Edema of interphotoreceptor matrix, distinct GCL, INL, ONL, and RPE (with some thinning of RPE in places) and distinct choroid. Rod labeling was found throughout the complete end Conc labeling with advience more immersion ends
- cell. Cone labeling with red/green opsin was present. Perifovea: Fibrovascular scar between Bruch's membrane and the retina. This area had a thinned
- RPE and no photoreceptors. Prominent inner layers of retina were present. Labeled rod photoreceptors were disorganized with displaced expression persisting in rod nuclei. There was a significant decrease of cones labeled in the perifovea and cones were absent near the fibrovascular

# The retina of Donor 2 (Ile201ThrVMD2 mutation) showed:

- No pathology by Fundus/SLO imaging. Periphery: Distinct GCL, INL, ONL, RPE and choroid. Drusen was observed in this eye. Rod
- labeling was restricted to the outer segment with reduction in the signal. Cone labeling with red/ green opsin was the same as in Donor 1. Perifovea: Prominent lamina, and thinned, yet robust, RPE and normal choroid. Labeled rod
- photoreceptors were disorganized with displaced expression persisting in rod nuclei. No cones evident.

# Abstract

# Fundus & SLO Images of Donor Eyes

# **Purpose:** To define the histopathological features in donor eyes from a patient with Usher syndrome type 2 caused by mutations in USH2A and GPR98.

<u>Methods</u>: Eyes were obtained from a 60 year-old female and were fixed within 25 hours from death. Globes were evaluated with macroscopic, SLO and OCT imaging. Perifoveal and peripheral retina were processed for electron microscopy and immunocytochemistry using cell-specific antibodies. Three age-similar (61, 65, and 70 year old) normal eyes were used as controls. DNA was obtained from blood samples of the donor and analyzed using the OtoSCOPE\* platform that includes 66 of the most common hearing loss genes. Segregation analysis was performed by testing this donor's affected son and unaffected daughter's samples for the two

mutations identified in the donor. Results: DNA analysis of the donor identified a heterozygous p.Gly2109Ser mutation in USH2A and a heterozygous p.Gln4989Stop mutation in GPR98. The donor's affected son also carried these two mutations. Her unaffected daughter did not carry either. AF-SLO was unable to delineate the macular lutea pigment and showed some mild degeneration around the optic disk. OCT showed areas around the fovea and optic disk with a thin photoreceptor layer. The peripheral retina was still intact but lacked structural features (i.e. an ellipsoid hand). In the periphery, histology showed distinct GCL and INL, but the ONL was reduced to 3-5 nuclear rows. In addition, several patchy areas of photoreceptor loss were noted. Prominent GCL and INL were present in the perifoveal retina, but the ONL retained only scattered nuclei. The RPE was thin but the choriocapillaris was present and robust. No cone opsin or cone arrestin labeled cells were observed in the macula, but a few highly disorganized cone-specific cells were present in the periphery. No rhodopsin-positive cells were observed in the macula, but were evident in the peripheral retina. Conclusions: The histopathology of the retina in a patient with Usher syndrome due to digenic USH2A and GPR98 mutations displayed a highly degenerated perifoyeal retina with preservation of some peripheral cone and rod photoreceptors. To our knowledge, digenic Usher syndrome has not been previously described due to molecular interactions between the USH2A and GPR98 genes. # Pedigree

Figure 2: Ex trive imaging of donor and age-similar control (ves. Macroscopic findus and SLO images were collected using an Axica Cam MRCS camera and video zoom lens (Zeiss) and a model HRA2 SLO (Heidelberg Engineering), respectively. All leves showed areas of artificit (elicatherl terting, vide to fixation and processing. All imaging modalities indicated that control eyes (A-B, E-F, I-J) are free of retinal pathology with exception of 3 small posts of hemorrhuge (A, B-arrows). Macula lutea are present with AF-SLO in controls, indicating a normal retina (1J). Images with the exception of atrophy surrounding the optic disk. Fundus (CD) and AF-SLO (K,L) modes show hyper-reflective and hypofluorescent areas which indicate mild degeneration, respectively (arrows). Both donor eyes (OD-faint; OS-clearly still present) show a muclu lutea rain ground the forea.

# OCT Images of Donor Eyes

Figure 3: E: Fire imaging of the donor (E-11) and age-similar control vys (A-D) mine OCT. Spectral Domain-OCT Collected using the Model SDOIS system (Bioptigen, Inc.) with  $-7x^7mm$  field of view. Control eyes had intact retinais that (1) were still congruent with the RPE-dota of one of the system (Bioptigen, Inc.) with  $-7x^7mm$  field of view. Control eyes had intact retinais that (1) were still congruent with the RPE-dota of view. Control eyes had well-defined photoreceptor layer. (B, D-dark space above arrows). In contrast, retinai images from doner cyse (F, H) lacked a well-defined photoreceptor layer, suggestive of degeneration, relative to controls (F, H – minimal dark space above arrows with exception of detachments). Regions of retinal detachment (d) and elevated terina (') were also observed. These artifacts can likely be attributed to the stuse being in a compromised state (i.e. diseased) as well as form the post-mottem stresses of enucleation, fratiation and processing. Ex face view has a 1mm ruby sphere over the optic nerve disk for sale calibration (ON, flower (I), and dashed lines in *m face* images indicate B-scan location. S-scan scale bar is 0.5mm.

Figure 4: Deceneration in the retina of donor eves with LSRI24 and GPR88 mutations. Representative photomicrographic from toluidine blue stained plastic sections (1µm) of both the donor retinas and an age-similar control are shown for comparison. Morphology of the control retina in the periphery (1) and perifives (C, C) displayed buyed learnetristics including structural lamma consisting of retinal cells. In the periphery, histology of the donor retina showed distinct GCL and NL, but the ONL was reduced to 3-5 nuclear rows. In addition, several patchy areas of photoreceptor loss were noted (8, arrow) and the RPE was thinner (P) than in the control. Promisent GCL and NL, were present in the perifoveal retina, but the ONL retinand only scattered nuclei (D). The RPE was thin and absent in some areas but the choricognillaris was present and robust (D), gravetheads (GLC) argaino cell layer; NL= inner nuclear layer; ONL= outer nuclear layer; POS= photoreceptor outer segments; RPE – retinal pixement einthelium. Bars = Soum.

# Immunocytochemistry of Donor Eyes

Figure 5: Significant decrease in rods in the perifore a donor cress with USH24 and GPR98 mutations. Representative photomicrographs of cryosections collected from the agesimilar control and the affected donor. Sections are shown labeled with antibodies specific to rhodops in (Aus4888, green) while cell nuclei were labeled with TO-PRO-3 (blue). In the control retina, rhodopsin was restricted to the rod outer segments both in the periphery (A) and periforea (C). In the periphery of the affected donor (B) rhodopsin-labeled cells were detected in the periro (D). In the membrane is indicated by a hashed white line. GCL= ganglion cell layer, INL=inner nuclear layer, ONL= outer nuclear layer, POS = photoreceptor outer segments. Bag = 40µm.

Immunocytochemistry of Donor Eyes

Figure 6: Significant reduction in the cones in the periforce of donce exes with USH24 and GPR98 mathians, Representative photomicrographs of cryosections obtained from the donor and an age-similar control. Sections were labeled with antibodies specific to red/green cone opin (ALCANAS, green) and GPAP (ALCANAS), red) while cell nuclei have been labeled with TO-PRO-3 (blue). In the control retina, red/green cone opin distribution was restricted to the come outer segments loth in the periphery (A) and performed (C). Few comes were still persent in the periphery of the donor retinas but red green cone opin was distributed to the photoreceptor inner segments (B, arrows). In contrast, no red/green opsin-labeled cells were present in the perifova of the donor (D). The Multer cells had undergone reactive gliosis throughout the retina and their hypertrophic processes were GFAP positive in the periphery (B) and perforva 01) of the affected donor when compared to the control retina (A, B). GCL= ganglion cell layer, INL= inner nuclear layer; ONL= outer nuclear layer; POS = photoreceptor outer segments. Bar = 40µm.

# Conclusions

An eye donor affected with digenic Usher syndrome due to USH2A and GPR98 mutations showed the following: • Overall, a more severely degenerated perifoveal retina compared

- to the peripheral retina
- · Atrophy around the optic disc
- · Absence of a well-defined photoreceptor layer
- ONL degeneration with localized loss of photoreceptors in the
- · 1
- periphery
- · Total absence of rods in the perifovea
- · Positive GFAP staining indicates the Muller cells had gone
- through gliosis in response to the retinal degenerative disease

# RETINAL HISTOPATHOLOGY IN EYES FROM A CARRIER OF XLRP WITH AN RP2 MUTATION

Cleveland Clinic

Gayle J.T. Pauer<sup>1</sup>, Vera L. Bonilha<sup>1</sup>, Mary E. Rayborn<sup>1</sup>, Brent A. Bell<sup>1</sup>, Meghan J. Marino<sup>1</sup>, John R. Heckenlively<sup>2</sup>, Elias I. Traboulsi<sup>1</sup>, Stephanie A. Hagstrom<sup>1</sup> and Joe G. Hollyfield<sup>1</sup> <sup>1</sup>Cole Eye Institute, Department of Ophthalmology, CCLCM, Cleveland, OH; <sup>2</sup>Department of Ophthalmology and Visual Sciences, University of Michigan, Ann Arbor, MI.

# Abstract

# <u>Purpose</u>: To describe the histopathological features of donor eyes from a carrier of X-linked retinitis pigmentosa (XLRP) with an *RP2* mutation.

Methods: Eyes were obtained from a 90 year-old and fixed within 25 hours postmortem. Globes were evaluated with macroscopy, SLO and OCT imaging. Perifoveal and peripheral retina were processed for electron microscopy and immunocytochemistry using cell-specific antibodies. Three age-similar normal eyes were used as controls. Genetic testing was performed on the family using sequence analysis. The donor was reported to have a macular dystrophy late in life. Therefore, her DNA was also genotyped for the high risk AMD SNPs rs1061170 (CFH), rs10490924 (ARMS2), rs11200638 (HTRA1), and rs2230199 (C3), using TaqMan SNP genotyping asays.

Results: Genetic analysis identified a heterozygous 2 bp insertion in the RP2 gene, c.77insCA. She was heterozygous at the CFH Y402H and C3 R80G sites and homozygous for the non-risk alleles at the A69S ARMS2 and promoter HTRA1 sites. The fovea and optic nerve could be clearly identified by all imaging modalities. IR and red free-SLO identified hyper-reflective lesions adjacent to the macula and ontic disk. OCT identified these lesions as retinal deposits extending from the RPE to the OPL. Histology of the peripheral retina showed a distinct GCL\_INL and ONL\_Patchy areas of photoreceptor loss associated with gliosis were noted in the retinal periphery. Prominent GCL and INL were present in the perifoveal retina in addition to gliosis associated with a fibrovascular scar. A serous detachment was present near the fovea, containing material stained with toluidine blue, except proximal to the RPE where blister-like projections were visible along the apical surface. Patchy, highly disorganized cells labeled with cone opsin and cone arrestin antibodies were present in the perifovea; however cone-specific labeled cells appeared normal in the periphery A few disorganized cells labeled with rhodonsin antibodies were detected in the perifovea but were more abundant and rod-shaped in the periphery

Conclusions: The histopathological features identified in this donor, including the loss of photoreceptors in the peripheral retina, indicate the retraind degeneration is likely due to XLRP. Although the genetic screening suggests a low risk of developing AMD, the fibrovascular sear indicated a previous hemorrhage followed by fibrosis consistent with wet AMD.

Figure 1. Pedigree of family with X-linked retinitis pigmentosa (XLRP) due to an *RP2* mutation. (Genetic analysis of the family identified a heterozygous 2 bp insertion in the *RP2* gene, c.77insCA (Mears et al, 1999 AJHG 64:897-900). ★ = eye donor

# Fundus & SLO Images of Donor Eye

Figure 2. Ar viro imaging of donor and age-similar control eves. Macroscopic fundus and S1O images were collected using an Assica mMRCS camera and video zoom lens (2 Ceiss) and a model IRA2 S1O. (Heidelberg Engineering), respectively. All eyes showed areas of artifact (detached retime, d) due to fixation and processing. All imaging modalities indicated that control eyes (A. B., E.F. J.) are free of retinal pathology. In contrast, images from the donor eye identified atrophy (fundus and IR-S1O - white, hyporeflective areas. AF-S1O - datk hyporeflective areas) in multiple regions including the macula, perimacula and areas surrounding the optic nerve. Imaging with different modalities provided additional information in regards to the retinal pathology as both pronounced and subtle differences between the right and left eyes could be observed between fundus and SLO. Postmortem imaging using these three wagast ged different states of disease progression in various locations of the retina, or in right vs. left eye of the donor.

# OCT Images of Donor Eye

# Control (OD) Control (OS) Donor (OD) Donor (OS)

Figure 3. Ex Vivo imaging of the donor (E-H) and age-similar control eyes (A-D) using OCT. Spectral Doman-OCT mages were collected using the Model SDOIS system (Bioptigen, Inc.) with  $-7\kappa7$  mm field of view. Control eyes that dirate retinas that (1) were still adherent and congruent with the RPE-choroid complex, (2) contained normal appearing laminar morphology, and (3) showed evidence of a well-defined photoreceptor layer (B) - 3 dark space above arrows). In contrast, retinal images from donor eyes (F, H) lacked a well-defined photoreceptor layer relative to controls (F, H — innimal dark space above arrows). Regions of retinal detachment (d) and elevated retina (^), were also observed. Dashed lines in *Enface* image indicates B-scan location; fovea (1), optic nerve (ON), B-scan scale bar is 0.5 mm.

**Histology of Donor Eye** 

Figure 4. Degeneration in the retina of donor eves with an RP2 mutation, Representative photomic cognapts from toludine bue stained platistic sections (1µm) of both the donor retinas and an age-similar control are shown for comparison. Morphology of control retina in the periphery (A) and periforwa (C) displayed dyrigical characteristics including structural lamina consisting of retinal cells. Histology of the donor retina revealed a distinct GCL, INL, and ONL. Patchy areas of photoreceptor loss associated with gliosis (B, thick arrow) were also noted in this region. Prominent GCL and INL were present in the perifoveal retina of the donor in addition to gliosis associated with a fibrovascular szer (D, thin arrow). A serus dateLahment was present near the fovea, containing material stained with toludine blue, except proximal to the RPE where blisterlike projections were visible along the apical surface (E, arrowheads). GCL = ganglione Ill ayer; INL = inten ranclear layer; ONL = outer nuclear layer; POS = photoreceptor outer segments; RPE = retinal pigneme tiphtelium; (Ch = choroid. Bars = Soµm.)

# Immunocytochemistry of Donor Eye

Figure 5. Significant decrease in rods in the perifove af denor eves with an RP2 mutation, Representative photomicorgraphs of cryosections coellected from the age-similar control and the donor. Sections are shown labeled with antibodies specific to rhodopsin (Alexa488, green) while cell nuclei were labeled with 70-RPO-3 (hue). In the control refine indoopsin was restricted to the rod outer segments both in the periphery (A) and perifovea (C). In the periphery of the donor (B) rhodopsin was also distributed to the photoreceptor inner segments (arrows). In the perifovea several very disorganized rhodopsin-labeled cells were detected in the edge of the serous detachment present near the fovea (D). Bruch's membrane is indicated by hashed white line. GCL = ganglion cell layer; INL = inner nuclear layer; ONL = outer nuclear layer; POS = photoreceptor outer segments; RPE = retinal pignent epithelium. Bar = 40µm.

Immunocytochemistry of Donor Eye

Figure 6. Significant reduction in the cones in the perifove a of donor exes with an R/2 mutation, Representative photomicrographs of cryosocitions obtained from the donor and an age-similar control. Sections were labeled with anthodics specific to red/green cone opsin (Alexa488, green) and (GAP (Alexa594, red) while cell nuclei have been labeled with TO-PRO-3 (blue). In the control retima, red/green cone opsin (Alexa494) (blue) and the operative of the operative distributed along the entire plasma membrane of this cone type (B, arrows). In contrast, few highly disorganized red/green opsin-labeled cells were present in the edge of the serus detahment near the fovea (D). The Muller cells had undergone reactive gliosis throughout the retina and their hypertrophic processes were GFAP positive in the perifovea (D) of the donor but not in the control retima (A, C). Bruch's membrane of its and their hypertrophic processes gangion cell aver; INL = inner nuclear layer; CON = outer nuclear layer; CON = photoreceptor outer segments; RPE = retinal pigment epithelium. Bar = 40m

# Conclusions

# A Carrier of XLRP with an RP2 mutation showed:

- Atrophy in the macula, perimacula and area surrounding the optic nerve
- Imaging of both eyes was not identical; this may be due to X-inactivation
- · Lack of a well defined photoreceptor layer
- · Patchy photoreceptor loss associated with gliosis
- · A fibrovascular scar associated with gliosis
- Serous detachment near the fovea
- Rhodopsin-labeled inner segments in the periphery
  Red/green cone opsin distributed along the entire plasma
- membrane
  Muller cells have undergone reactive gliosis throughout the
  retina

# Immunohistochemistry of Donor Eyes Immunohistochemistry of Donor Eyes

# Abstract

Purpose: To define the retinal histopathology in donor eyes from a atient with a cone dystrophy of unknown genetic origin. Methods: Eves were from a 54 year-old female, fixed within 13 hours ostmortem. Globes were evaluated with macroscopic, SLO and OCT imaging. Perifoveal and peripheral regions were processed for electron microscopy and immunocytochemistry using cell-specific antibodies. Two age-matched normal eves were used as controls. DNA was obtained from blood samples of the donor and analyzed for 26 cone dystrophy genes by next generation sequencing.

Results: Fundus macroscopy and SLO showed an abnormal ring encompassing the macula and centered on the foyea. OCT showed retinal thinning in this region. Histology confirmed the presence of this lesion which measured ~5 5mm in diameter. There was an abrunt transition at the periphery of the lesion. Outside the lesion several row of nuclei were present in the ONL, but within the lesion, only occasional patches of stubby cones projected from the outer limiting membrane.Immunocytochemistry revealed patches of cone arrestin labeled cells in the lesion but this labeling was reduced in the periphery. Co-labeling with cone opsin antibodies was not observed in these cells. Rhodopsin-positive cells were rarely observed in the central lesion, but were prominent throughout the rest of the retina. DNA analysis failed to identify a mutation in any of the genes analyze (ABCA4 ADAM9 AIPL1 BESTL c80RF37 CACNA1E CACNA2D4 CDHR1, CERKL, CNGB3, CNNM4, CRX, GUCA1A, GUCY2D. KCNV2, PDE6C, PDE6H, PITPNM3, PROM1, PRPH2/RDS, RAX2, RDH5, RIMS1, RPGRIP1, SEMA4A, and UNC119). Molecular analysis of additional retinal dystrophy genes is currently pending. Conclusions: The histopathology of the retina in a patient with a cone dystrophy of unknown genetic etiology displayed a central lesion characterized by degenerated cones and the absence of rod photoreceptors.

OCT Images of Donor Eyes

Figure 2. Ex Vivo OCT imaging of the donor (B,CE, F) and an age-similar control eye (A,D). The control eye (A, D) had an intact retina that (1) was still abherent and congutent with the RPE-chored complex. (2) showed is dratation artifield due to NN-fove a traction from tissue above arrows), and (3) showed a fraction artifield due to NN-fove a traction from tissue above arrows), and (3) showed a fraction artifield due to NN-fove a traction from tissue abive arrows), and (3) showed as usale reference (A). In contrast, the B-scain images from sphere positioned over the ON as a scale reference (A). In contrast, the B-scain images from common (b) showed on an abivity and invide the due of the obtained of an invite (A) and the due of the obtained the due of the obtained of the obtained of the obtained of the obtained (A) and (A) a compared to the control eve. Regions of retinal detachment (d) and elevated retina (^) were also observed as a result of fixation and processing. Broken lines in *en face* image indicates B-scan location, optic nerve (ON), B-scan scale bar is 0.5mm (F).

Figure 4. # **Clinical Summary of Donor**

# Last Eye Exam at age 54 years (data extracted from redacted medical ecords): Visual Acuity: 20/50 OD and 20/40 OS IOP: 17 OD and 19 OS

- Anterior Segment: normal OU Dilated Fundus Exam: Nerve no disc pallor or edema OU
- Vitreous clear OU Retinal vessels normal OU Macula – no hemorrhage or subretinal fluid. Significant for Bull's eve RPE changes OU
- Perinhery no holes or tears

- Perphery no noise or tears
   Piouroscein Angiography Findings OU normal AV transit and choroidal filling.
   Late leakage consistent with NVD. Transmission defects consistent with RPE changes
   Medical History hypertension and acid reflux, otherwise noncontributory
   Family History AMD (cone dystrophy) in sister and brother .

# Conclusions

- The post-mortem analysis in this donor's retinas supports the clinical diagnosis of cone dystrophy. The retinas had a central lesion characterized by degenerated cones
- and an absence of rod photoreceptors. This correlated to the medical record description of Bull's eye RPE changes in the macula.
- The underlying genetic etiology in this patient remains unknown. There were no detectable mutations in 26 cone/cone-rod dystrophy
- associated genes suggesting the possible involvement of a novel cone dystrophy gene or a mutation(s) in a gene described as causing a roddystrophy that is causing a unique phenotype.

# Abstract

Purpose: To define the morphology and distribution of photoreceptor markers in a donor eye from a female symptomatic carrier of choroideremia with an X linked choroideremia. This donor was a female symptomatic carter of choroidsemia with an X linked choroidsemia. This door was a member of a family with multiple female carters have macanic dystanction. Methods: A nulti-generation family with X-linked choroidsemia was evaluated over two decades with dialest Intuits examination, choropostphy visual field testing and electroenforography. A family history was obtained, and molecular testing was performed. The door of deal at get 91 and eyes were fixed in A family anternotation effort of 25 signatization (e) in plonghas builty. Parafitm tasses a different areas of the eye were studied by indirect minundhursescence, using well-characterized monoconia antiboties to the core and ord plopetin matters. Nor, regenerative samples were samples were the studied by indirect minundhursescence, using well-characterized monoconia antiboties to the core and ord plopetin matters. Nor, regenerative samples were samples were the samples were the studied by indirect minundhursescence, using well-characterized monoconia antiboties to the core and relative samples were samples were the samples were samples samples were samples samp monochal antibodes to the cone and rold specific markers. Also, representative samples were processed for electron microscopy markers. **Results**, **14**, **86**, **77**, thinds examination revealed a relocat properties relenged with thindess and a displicant central vision impairment. Molecular testing morphological analysis of the doors revealed **PEE**: thinning and papert clumping hypotol for choroideness, and well aphotometer degeneration in some meres and basal immar deposits. In addition, a grieft number of dusame was observed in the door's fores. Labeling of the sections with the core copplication transfer revealed to officiences where meres and basal immar deposits. In addition, a grieft number of dusame was observed in the door's fores. Labeling of the sections with the core copplication transfer revealed to officiences where a docessed targets. All, onbogs may almost completely absent in the affected relina. Moreover, redigreen optims were distributed along the entire plasma merenter of conset with the grament type in all cheareed areas. **Constraintson**, allow distributed along the entire too plasma membrane in all the observed areas. **Constraintson**, counter doors. Anyweir, the histogical did activated suspects that the chinal meterstation of the meters down amerew. The histogical did activater suspects that the chinal meterstation of the sume form. However, the histogical did activater suspects that the chinal meterstation of the sections. carrier donor. However, the histological data obtained suggests that the clinical manifestation of this fonor seems to be related to abnormal distribution of both cone opsins and rhodopsin.

# Introduction

Choroideremia is a rate X-Inikid recessive retinal degeneration characterized by progressive atrophy of the photoeceptors, the RPE, and choroid in affected men, resulting in severe loss of vision. Typically, females certise are moasics due to loyorization (radiom inactivation of one X choronsome in each cell early in felal development) (Lyon, 1981). Expansion of the severe in the severe interval of the severe interval of Reb gerangingenty/mentations, retered to a Reb ecot protein (REP1) (Saskar et al. 1995; Sashar et al., 1995; vision den Hurk et al., 1997). However, it is not known how the matation in this protein leads to the degeneration of the choroid, RPE and retera. Female carriers usually show fundus charges, including patchy degigementation of the RPE and coarse apprehetary paralistip in the periative typical state the matarix Achomosome. Female carriers are generally unaffected, atthough affected females have been decribed in the Instrume. ibed in the literature

The planetine with chronotenenia, show complete loss of the chronic and of all the outer relate, displaying at this line of attopic timer relies hying against the sclera (Onbat and McCuldon, 1980). Cameron et al., 1987; Rodrigues et al., 1984). The complete atrophy of the relina and chronic in mate patients percludes controlling on the planetic scheme scheme scheme scheme scheme the present study we analyzed the morphology and distribution of photoreceptor markers in a donor eye from a female symphomatic carrier of kinked chronicements.

# Summary

- Histopathological analysis of the choroideremia affected retina revealed the presence of different degrees of degeneration in the several areas analyzed: - The retina displayed areas of severe degeneration, with n
- photoreceptor outer segments, photoreceptors nuclei atrophy, and atrophy of the inner retina. On the other hand, other areas displayed close to normal retina.
- The RPE displayed severe atrophy, thinning, pigment clumping and sub-epithelial debris deposition in all the areas observed. The choroid displayed light signs of degeneration.
- Labeling of the affected retina with a cone cytoplasmic marker did not reveal any significant cell body difference from the contro sample (data not shown).
- Red/green opsins are distributed along the entire plasma membrane of this cone type, from the tip of the outer segment to the synaptic base.
- Blue opsin expression is almost completely absent from the affected retina. Very few cones could be observed still expressing blue opsin in all the 3 different areas analyzed; in these cone cells blue opsin was detected both in their inner and outer segments.
- Rhodopsin was also found to be distributed along the entire plasma membrane of the rods, from the tip of the outer segment to the synaptic base.
- Utrastructural analysis of the affected macula revealed the abscence of RPE apical microvili and basal infoldings, instead, RPE's basal surface and choroid displayed the presence of banded fibers composed of clumps of wide-spacing collagen. Bruch's membrane was filled with vesicular structures, some smooth and others like briste-coated vesicles.

# Cleveland Clinic

# Abstract

Purpose: To evaluate the histopathology in donor eyes from a patient with autosomal recessive retinitis pigmentosa (arRP) caused by EYS mutations. Methods: Eyes were obtained from a 72 year-old female who died from pancreatic cancer. Eves were fixed in 4% paraformaldehyde and 0.5% glutaraldehyde in PBS within 6 hours postmortem. Globes were evaluated with macroscopic, SLO and OCT imaging. Macula and peripheral regions were processed for electron microscopy and immunocytochemistry. An age-matched normal eye and the eye donated by donor's asymptomatic mother were used as controls. DNA was obtained from blood samples of the donor, her affected brother and sister, and two unaffected sisters. Direct genomic sequencing of the 19 arRP genes was performed.

Results: DNA analysis of the affected brother revealed the novel EYS gene mutations, IVS11+1G>A and Q874X. Imaging revealed peripheral bone spicules and RPE atrophy immediately surrounding the optic nerve and macula. SLO showed demarcated, circular patches of hypofluorescence in the perimacula region of both eyes, suggesting focal loss of RPE as choroidal vasculature could be visualized. Histology revealed a highly degenerate retina with little evidence of stratified nuclear layers in all peripheral areas studied. In contrast, the macula and perimacula region contained well organized ganglion cell and inner nuclear layer with only a few nuclei remaining in the outer nuclear laver. The RPE was thin in the macula and absent in the far periphery. An amorphous material was present between the degenerate retina and the RPE in the macula. Rhodopsin labeled rods were absent except in the far periphery. Cones labeled with opsin and arrestin antibodies were present in the macula, but were mostly absent from the periphery. Cone synapses and outer segments were not observed. Calbindin D labeled second order neurons were unevenly distributed in the periphery.

Conclusions: Advanced retinal degenerative changes with near-total absence of rods and preservation of macular cones characterize the retinal histophathology of and arRP patient due to EYS mutations.

# Introduction

Mutations in 34 different genes cause autosomal recessive RP (https://sph.uth.tmc.edu/retnet/). Together these account for approximately 50% of the arRP cases. Recently, the eyes shut homolog (EYS) gene was identified at the RP25 locus (Abd et al., 2008; Collin et al., 2008). Mutations in the EYS gene account for approximately 5% of arRP cases (Littink et al., 2010).

Human EYS protein is localized in the photoreceptor outer segments (Abd et al., 2008), However, the function of the protein in the retina is still unknown. Here we report for the first time, the distribution of photoreceptors and other retinal cells in an adult donor carrying two novel EYS gene mutations.

# (1) Pediaree of Family Studied

Pedigree of family with autosomal recessive RP due to a EYS mutations, Stashed symbols reflect deceased family members. Affected family members are shown in black and unaffected family members are shown in white. DNA analysis was carried out in all three affected members (III-5, III-6, and III-7), in their two unaffected living siters (III-8 and III-9), and in their mother (II-10); EYS mutation was initially identified in III-5. The postmetime many site in this study was done on unaffected carrier nember II-10 (\*\*) and affected member III-6 (\*).

(2) Fundus Images of Donor Eye

In situ imaging of whole EYS arRP donor and age-matched control eyes, SLO and In situ imaging, of whole EYS arRP donor and age-matched control eyes. SI:O and macroscopic funduus images were collected by using a model HRA2 control age and plaser ophthalmoscope (Heddeberg Engineering, Inc.) and Zeiss AkoCan MHCS camera escipped that macro who ones, model. Bryline one coups how control age of the macro were plane, and the second second age eliminate specular reflections and improve contrast and image quality. To accomplish SI:O imaging the entire instrument war critical 90% should be scan direction is perpendicular to the table surface for optimal imaging of the PBS filled eye cups. All imaging imposed in critical plane instrument war critical 90% should be scan direction is perpendicular to the table surface for optimal imaging of the PBS filled eye cups. All imaging modalities revealed bone splucies in peripheral regions. SI:O-H is howed demaracted; circular patches of hypothurescence in the perimacula region of both eyes, suggesting focal loss of RPE as choradid vasculature could be visualized. SI:O-AF imaging revealed the root compared to the control which clearly showed retinal vasculature. Scale bars in fundua image = 0.5 cm.

Degeneration in the retina of an EYS arRP donor, Representative photomicrographs from toluidine blue stained plastic sections (1µm) of both the arRP donor (B, D), matched controls (A, C), the unaffected mother of the donor (F) and an older (88 y.o.) age-matched control (E) nas. Morphology of control retina in the periphery (A) and perimacular (C) region displayed cal characteristics including structural lamina consisting of retinal cells. The arRP donor pical characteristics inc tina in the periphery (B) became atrophic with disorganization of the lamina and cellula vers, gliosis, and presence of intraretinal bone spicules, usually associated with bloo sels (\*). In contrast, a prominent inner and outer nuclear laver was present in th construction (): a region (Du.2 as proton strategies of the set macua () i the Pre was leduced under thoma uncevent and the permitate and unit and continuous in the epichery. The unaffected mother of the arRP donor displayed significant rease in the nuclei in the inner and outer nuclei layers. In addition, this retina displayed elin artificat in subtential space (4), GCL- gangino cell layer, INL= inner nuclear layer; L= outer nuclear layer; RPE= retinal pigment epithelium. Bars = 50µm.

# (5) Immunocytochemistry

sence of rods in both the periphery and perimacula of EYS arRP donor. epresentative photomicrographs of cryosections collected from the matched control (A, C), e arRP donor (B, D), the unaffected mother of the donor (F) and an older age-matched nrtol (E). Sections are shown labeled with artibodies specific to N+arminal domain of odopsin (Alexa488, green) while cell nuclei were labeled with T0-PRO-3 (blue). Sections ere imaged using a Leica laser scanning confocal microscope (TCS-SP2, Leica, Exton, PA). A series of series of 1 µm xy (en face) sections were collected. Each individual xy retinal image presents a three-dimensional projection of the entire section (sum of all images in the represents a time-contensional projection on the entire sector (sum or as maps in the stack). Comparison of the samples showed that redooptin expression was absert in both the periphery (B) and perimacula (D) of the arRP donor refins. Control samples (A, C, E) and the unaffected mother (F) displayed frozophi distribution excited to the roots dure sagnets. However, the unaffected mother displayed significant decrease in the nuclei in the inner and outer nuclei layers. Bar + 40µm.

ations of cones in the perimacula of the EYS arRP donor retina Bigurantiative photomicrographs of crystections scalected from a matched control (6, (5, the artPf down (6, 0), the unaffed and the down (7) and and down ag-matched control (6). Sections are shown labeled with antibodies specific to core arresin (Assx488, green) and redgreen opsin (Assx584, red) while cell nuclei were labeled with TO-PRO3 (blue). Images were obtained using the same methodology previously advermentioned in Figure 5. Core arresin was distributed along the entire plasma advermentioned in Figure 5. Core arresin was distributed along the entire plasma the same methodology previously nembrane of this cone type, from the tip of the outer segment to the synaptic base while he red/green opsin was restricted to the cone outer segments in the control retina both in the periphery (A) and perimacula (C), in the unaffected donor mother (F) and the older perpicery (A) and perimacula (C), in the unaffected donor mother (F) and the older tabled control (C). These samples also displayed redigreen opsin restricted to the fer segments. Conces were mostly absent from the periphery of the arRP donor retina ), incontrast, conces were present in the macular region of the arRP donor (C), but they tre clearly disorganized and morphologically different than controls. In addition, rangic terminals were not visualized as well. The unaffected mother (F) displayed pared similar locaries in the inner and outer nuclei layers but otherwise peared similar to controls. Bar + 40µm.

# (7) Immunocytochemistry

Presence of amacrine, bipolar and Müller cells which have undergone reactive posis in EYS arRP donor eves. Representative photomicrographs of cryosections lected from the matched control (A, C), the arRP donor (B, D), the unaffected mother of the donor (F) and an older age-matched control (E). Sections were labeled with antibodie specific to calbindin D-28K (Alexa488, green) and GFAP (Alexa594, red) while cell nucle re labeled with TO-PRO-3 (blue). Sections were analyzed using a Leica laser scanning were labeled with TO-PRO-3 (blue). Sections were analyzed using a Leica laser scanning notocal microscope. Images were obtained using the same methodology previously disrementioned in Figure 5. Comparison of the samples revealed that cabineli tables and the control releas was present in the macrine, bipolar and photoreceptor cells, whereas IFAP was restricted to only astrocytes within both the periphery (A) and perimacula (D). The older control [36] and unafteded motive of the arMP once (F) as do digited similar simblicion of both markers. However, in the periphery (B) and perimacula (D) of the arMP, cabine how of the arMP once) and the outperiod of the arMP once (C) and the same simplicion of both markers. However, in the periphery (B) and perimacula (D) of the arMP, cabine how offset on early and the same simplicion and the same sis the same simplicion an

# Conclusions

# The retina of an adult arRP donor with two novel EYS mutations displays:

- atrophic retina with disorganization of the cellular layers, gliosis, and presence of intraretinal bone spicules in the periphery;
- reduced thickness of the RPE in the perimacula and thin and discontinuous RPE in the periphery;
- · absence of rods in the perimacula and periphery;
- significant decrease of cones in the periphery;
- · presence of disorganized, morphologically different cones in the perimacula;
- distribution of calbindin D-28k positive cells throughout the whole retina:

 Müller cells which have undergone reactive gliosis throughout the retina, and their hypertrophied throughout the retina, and processes were GFAP positive.

The retina of the unaffected mother of the arRP donor displays:

- typical characteristics including structural lamina consisting of retinal cells;
- significant decrease in the nuclei in the inner and outer nuclei lavers;
- myelin artifact in subretinal space;
- similar to control distribution of rhodopsin and red/green cone opsin proteins (restricted to the outer seaments):
- similar to control distribution of calbindin D-28K positive cells and GFAP labeling.

# Abstract

Euroses: Patients with Goldmann-Fave syndrome carry matistors in the M2E2 gave. This goes codes for a photoreciptor-specific moleclar receptor. The present study aimed to analyze the distribution of rods, cones, and the redigreen and blue opsins in the eyes of a door with Goldmann-Fave syndrome. The patient was 88 years-old at the time of his death. His clinical phonotype, including an early history of night blindness, peripheral retinoschilais and midphetipheral plumping of pipmet were characteristic of the Goldmann-Fave syndrome. He was Sound to have a homozogous splice site matistion in the IM2E2 gene. <u>Mathada</u>: The affected eye was fixed in 4% processed of transmission electron microscopy (TEM). Alternitarly, cronotal tissue sections of the macula and periphery were studied by indirect immunofluorescence, using weir-characterized monoclonial antibides to the rhodgreen (AB5405) and blue (AB5407) opsins. The affected dorror eye was compared to a matched normal eyes. <u>Realists</u>: The entities was highly discognized with indistrict layers. Bione spocie pipment was observed both in the perimacular and periphery of the eye. The PEE layer was discontinuous in nome regions of the perimacular and periphery of the eye. The entitle redifference of conse were observed in the perimacular area. Both nedlygeen and blue opins were distribuied along the concever in the perimacular area. Both nedlygeen and blue opins were distribuied along the entire cellular expanse of the cone photococeptors in the affected eye. blue were studied and the cone options of the conserve in the perimacular area. Both nedlygeen and blue optims were distribuied along the entire cellular expanse of the cone photococeptors in the affected eye. Buy were standed and blue come options of the cone photococeptors in the disclosed eye. Buy were tailowed an absence of rods and abnormal distribution of redgreen and blue cone options.

Supported in part by NIH grant EY015638, a Research Center Grant from The Foundation Fighting Blindness and Research to Prevent Blindness.

# Introduction

The Goldmann-Favre syndrome was described from two separate reports in 1957 (Goldmann, 1957) and 1958 (Favre, 1958) describing a teenage borber and ister, respectively, with a disinctive vitreoretinal degenerative disorder. The Goldmann-Favre syndrome is a rare autosomal recessive intercentian degenerative vitreored by night bildness, pigmentary degeneration, macular and peripheral retinoschisis, posterior subcapsular cataract, markedly abnormal or nondetectable electrograms, and degenerative vitreous changes, subt. Si loyable. Si loyable. Si loyable disorse that degenerative vitreous changes, such as loyable. The single size of the single and the change of the single size of the size shows been reported confirming that this is a clinically recognizable disease. However, this been show that the clinical descriptions are significant. Later on, it was proposed that the Goldmann-Favre syndrome is a type of enhanced S come syndrom since in both retianl systemicions the patient display hypersensitivity to bulk light and their

Later on, it was proposed that the Goldmann-Favre syndrome is a type of enhanced S cone syndrome since in both retraind systanctions the patients display hypersensitivity to bule light flashes than d their electroretinograms have greater amplitudes to short-wavelength (eg, blue) light flashes than to longwavelength (eg, orange) light flashes (Jacobson et al., 1991).

wavelengin (eg. orange) light lisables (Jacobson et al., 1991). The Goltmann-Pare syndrome is caused by loss-of-function multipling into the M2E25 gene (Ideo dependent transcription factor (Kohayashi et al., 1990). Reported results suggest that M2E25 context observes and the state of the M2E25 on the hordroceptor differentiation (Hadro et al., 2000; Cheng et al., 2006; Howere, it is not known how the multiplication in this protein leads to the degeneration of the choroid, RPE and relina. In the present that year analyzed the morphology of the relina and the distribution of photoreceptor in the present that year analyzed the morphology of the relina and the distribution of photoreceptor

markers in a donor eye from a male donor affected by Goldmann-Favre syndrome.

Gross pathology (A) and schema (B) of regions cut and processed for cryosectioning from an eye of a Goldmann-Eavre syndrome (GFS) donor. The anterior segment has been removed and the retina is viewed en /acc; characteristic pigmentary changes can be observed. Region 1= perimacular area; region 2= periphery. Bar = 0.5cn.

Begeneration in the retine of a Goldmann-Earce syndrome affected donor. Human hym plastic sections of both a matched control (A, B) and the affected GFS (C-F) relines stained with tokladine blue. (A, B) Morphology of control retina in the permacular region of the eye. (C-F) The m-inde of the affected GFS (C-F) relines of the state (E) demonstrated sparse inner and outer nuclear layers with stanted photore-splor inner and outer segments. A thin, restricted area of pipmented RFE cells was observed in the perimacular retina (C, small arrows) while a continuous layer of pipmented RFE cells was observed in the preprint and the indexided down (Hip magnification dowered and for affected retins in the preprint) (F) but not all before down and the presence of several toom spudie pipments (targe arrows) Bare 20pm).

Figure 1

Significant absence of cones in the periphery together with the presence of coseties of cones in the perimacula of a CFS affected doncy. Human cryosections of both a matched topological and the set of the se

ultrastructure of perimacula tissue was analyzed by TEM. Observation at both low (A) and high (B) anginization showed a collapsed RPE apiasi atradee mostly deprived of apical microvilli, no photoreceptor outer segments are observed on top of the RPE apical surface. Microsev, observation of RPE's basal surface revealed absence of basal infoldings (large arrows) Bruch's membrane was very discipanteed (A). Some areas displayed multi ayes of pagmented colls; (C, D). The pescente of disensionance (C, sand Bield with absormably large (-himn) spherical electronicense melaneomes (C, C). Blue conceptin is significantly increased and distributed along the entitie plasma marknare diffusion con type in a CBS affected dong. Human cryosections of both a matched control and affected GPS dong. When any set of the set of the concepting (AlexaekS, green) while call Incel were labeled with TO-PRO-3 (bite). Sections were analyzed using a Leica laser scanning confload microscope (ICS-SP2, Leica, Exton, PA, A) seeting of 11 microscope and the set of the sectors were analyzed using a Leica laser scanning confload microscope (ICS-SP2, Leica, Exton, PA, A) seeting of 11 microscope and the sectors (sum of all images in the table). Microscope panels were composed using AbbePhrotomotop 5.5. Comparison of the samples showed that blue cone opsins were significantly increased in all the observe rigoris of the affected eye, where blue cone of the outer segment to the synaptic base; the abromal distribution was also observed in opstein in the construction.

# Summary

 Histopathological analysis of the GFS affected retina revealed the presence of different degrees of degeneration in both areas analyzed:

 -sparse inner and outer nuclear layers with stunted photoreceptor inner and outer segments were observed; high magnification observation of the affected retina in the periphery but not in the perimacula revealed the presence of several bone spicule pigments.

 -a thin, restricted area of pigmented RPE cells was observed in the perimacular retina while a continuous layer of pigmented RPE cells was observed in the periphery.

Utstartuctural observation of the perimacular area revealed a collapsed RPE pacies surface mostly deprived of paired microvill and basal infoldings; no photoreceptor outer segments are observed on top of the RPE apais surface. Moreover, Bruch's membrane was very discoganized. Some areas displayed multi layers of paymentic cells. The presence of desmonses was cells, was filled with abnormaly large of the and spherical electroridence melanosanes.

Rhodopsin was mostly absent in the affected retina.

Labeling with a cone cytoplasmic marker revealed significant absence of cones in the periphery together with the presence of rosettes of cones in the perimacula of the affected donor.

Red/green opsins are distributed along the entire plasma membrane of this cone type, from the tip of the outer segment to the synaptic base. This distribution is also observed in the rosettes.

Blue opsin expression is significantly increased in the affected retina. Blue opsin was also distributed along the entire plama membrane of this cone type.

# Introduction

Leber Congenital Amaurosis (LCA) comprises a group of genetic disorders in which vision loss or dysfunction accurs early in life, often from birth. The extent of vision defects varies from patient to patient, but are usually quite severe. Currently matiators have been identified in 14 different genes in LCA patients and each is a recessive disorder (Cremens et al. 2002; den Hollander et al. 2008). Review of the lineature identified influence patiendogis gencemes hat must likely represent LCA and the several to the lineature identified more than the patient and the several to the

review of the metalute identified intreen participate spectra and the second se

wing. Analysis of the refinal histology of the reported LCA eyes suggests three possible disease categories (Roemekoop, 2004, den Hallander et al., 2006). Degenerations or abotropy (Aubheau, 1903, Sondy and Williams, 1900, Roci and Kuowashu, 1984, Francois and Hanssens, 1986, Pinacois and Hanssen Sondower and Sondower and Sondower and PPE layer they may be propuls, and abates and the sondower and the sondower and the sondower and the sondower and the conduction of the sondower and the sondower and the sondower and the sondower and report and the sondower and the sondower and the sondower and the sondower and the conduct as the sondower and the sondower

# Abstract

Purpose: To evaluate the histopathology in donor eyes from a patient with autosomal dominant retinitis pigmentosa (adRP) caused by a Pro23His rhodopsin mutation.

Methods: Eyes were obtained from a 72 year-old male who died from a stroke secondary to subdural hematoma. Eyes were fixed in 4% paraformaldehyde and 0.5% glutaraldehyde in PBS within 17.5 hours postmortem. Globes were evaluated with macroscopic, SLO and OCT imaging. Macula and peripheral regions were processed for electron microscopy and immunocytochemistry. Three age-matched normal eves were used as controls. DNA was obtained from blood and buccal samples of the donor, his affected daughter and son. Direct genomic sequencing of the entire rhodopsin coding region and flanking intronic sequences was performed.

Results: DNA analysis of the donor and affected family members revealed a rhodopsin Pro23His mutation. All imaging modalities revealed peripheral areas of heavy bone spicules. The area surrounding the optic nerve showed evidence of RPE atrophy as choroidal vasculature could be visualized. The fovea and optic nerve could be clearly identified with OCT. Histology revealed a highly degenerate retina with little evidence of stratified nuclear layers in all peripheral areas studied. In contrast, a prominent outer nuclear layer was present in the perifoveal region. The RPE was reduced from normal thickness in the macula and thin and discontinuous in the far periphery. Bone spicule pigmentation was extensive, and present throughout the degenerate retina in the periphery, usually associated with blood vessels. Cones labeled with opsin and arrestin antibodies were present in the macula, but were mostly absent from the periphery. Cone synapses and outer segments were not observed. A few highly disorganized, rhodopsin labeled rods were detected in the macula but were absent in the periphery. Calbindin labeled second order neurons were unevenly distributed in the periphery.

Conclusions: The histopathology of the retina in a patient with advanced Pro23His rhodopsin mutation displayed highly degenerate peripheral retina and preservation of some cone and rod photoreceptors in the macula

# Introduction

Between 15 and 35% of all cases of RP follow an autosomal dominant inheritance pattern (adRP). Currently mutations have been identified in 23 different genes in ADRP patients according to RetNet. The most common rhodopsin mutation in North America is Pro2311s, which is isound in about one third f patients with rhodopsin mutations.

Previous studies of ocular observation of affected patients suggested clinical heterogeneity even in related patients with this same point mutation in the rhodopsin gene (Berson et al., 1991; Aleman et

al. 2009; A few previous studies reported analysis of the retinal histology of eyes with Pro23His mutation. A common finding in those studies was variable histological findings in the retina with a final common pathway leading to photoreceptor cal death (Koh & Schurz, 1974. To et al. 2002. To et al. 2004). Here we analyzed and reported for the first time the distribution of photoreceptors and other retinal cells in an adult Poz2His RP donor.

# (1) Pedigree of Donor Family Studied

Pedigree of family with autosomal dominant RP due to a Pro23His Rhodopsin mutation. Stashed symbols reflect deceased family members. Affected family members are shown in black and unaffected family members are shown in white. DNA analysis was carried out in donor and his two affected children; Pro23His modopsin mutation was initially identified in donor IF/4% blowed by confirmation of the mutation in his two affected children. The postmortem analysis in this study was done on member II-7 (\*). Interview with family members suggested that I-1 (arrow) may also have been affected.

In situ imaging of whole Pro23His Rhodopsin adRP donor and age-matched control

In situ manina of whole Pro23His Rhodopsin adRP donor and aee-matched control ways. GUo and macroscopic lunds images were collected by using a model HRAC contocal caraning laser ophthalmoscope (Heddeberg Engreening, Inc.) and Zeiss Akidam MROS amera equiped with a macro video lensi, respectively, Princi to majarig the consea and lensi were removed leaving only the postetor pole. Remaining eye cups were filled with PBS to imitiante specular releations and improve contrast and manege quality. To accomplish SLO outroes for optimal imaging of the PBS littled eye cups. All imaging modalities revealed exclored in leavy to ma scinices SLO sill imaging includities revealed

strated or open and a set of heavy on or or to be may or oppy opposed in mitiging another is exclused exclusion of the oppic disk and the sypopigmented macula identified by fundus image (arrow). SLO-AF imaging revealed some weak autofluorescence (AF) signal that was devoid of any structural detail compared to the

control which clearly showed retinal vasculature and lipofuscin AF background. The area surrounding the optic nerve showed evidence of RPE atrophy as choroidal vasculature could

he visualized. Scale bars in fundus image = 0.5 cm

# POSTMORTEM ANALYSIS OF CONE OPSINS IN A PATIENT WITH AN AUTOSOMAL DOMINANT CONE DYSTROPHY. S. Grover<sup>2</sup>, V.L. Bonilha<sup>1</sup>, G.A. Fishman<sup>2</sup>, and J.G.Hollyfield<sup>1</sup> <sup>1-</sup>The Cole Eye Institute, The Cleveland Clinic Foundation, Cleveland, OH and <sup>2-</sup>Department of Ophthalmology and Visual Sciences, University of Illinois, Chicago, IL.

# ABSTRACT

Purpose: The present study aimed to analyze the distribution of the red/green and blue opsins in the cones from an eye of a patient with an autosomal dominant cone dystrophy. Methods: Eyes were fixed in 4% paraformaldehyde and 0.5% glutaraldehyde in phosphate buffer. Cryosections were studied by indirect immunofluorescence, using well-characterized monoclonal antibodies to the cone cytoplasm (mAb 766) and polyclonal antibodies to either red/green (UW-16 and p4924A) and blue (p108B) opsins. The affected donor eye was compared to a postmortem compatible normal eye.

Results: The patient's vision was corrected to 20/200 in each eye when last seen 3 years before his death at age 85. Visual field testing showing normal peripheral boundaries and central soctomas. ERG testing showed normal rod function while the cone b-wave amplitude was reduced 40% below the lower limit of normal. Fundus exam showed only isolated drusen within the macula. The normal-appearing fovea was a common feature in all affected family members. Blue opin was restricted to the outer segments of blue cones in the affected retina. In contrast, red/green opsins were distributed along the entire plasma membrane of cones with this pigment type. The cone pedicles appeared larger than normal. Conclusions: The histological data obtained suggest that the clinical manifestation of this dystrophy is related to an abnormal distribution of the red/green opsin. Additionally, changes in the cone pedicles may be correlated with the abnormal cone ERG in this patient. Supported by The Foundation Fighting Blindness, and The Grant Healthcare Foundation.

# **INTRODUCTION**

The cone dystrophies are characterized by biateral visual loss, colour vision abnormalities, central scotoma, variable degrees of nystagmus and photophobia, together with electrophysiological or psychophysical evidence of abnormal cone function. Cone dystrophies can show autosomal dominant, autosomal recessive, and X-linked recessive inheritance. There is clinical as well as genetic heterogeneity. Here we report the histological findings resulting from the analysis of both eyes of a member of a family with an autosomal dominant cone dystrophy.

# **FIGURE 1**

Also shown, the ERG from the right eye of one of his affected sons (family member V-2), showing normal amplitudes (right column).

Red distribution is normal in the affected retina. Human cryosections of both the matched control and affected family member (IV-1) were labeled with the cone interphotocecptor matrix (IPM) marker PNA (FITC; green) and an antibody specific to rhodopint (Alex354, red). Call nuclei were labeled with the cone markyred using 1 citcles are saming motion dimensione (TC-S27). Leice, ELON, PA). A series of 1 µm / or face) sections were analyzed using 1 citcles are saming motion dimensione (TC-S27). Leice, ELON, PA). A series of 1 µm / or face) sections were collected Each individual primage of the retines stander represents a three-dimensional projection of the entire cryosection (sum of all images in the stack). Microscopic panels were composed using Addeb/Hotolobp 55. Comparison of the semples showed that the one IPM diaplayed a heterogeneous distribution both in the macula and the periphery. In contrast, thedopsin staiming was not different from the control eye. Bar in the periphery pand = 20µm, bar in the macula and = 40 µm.

# SUMMARY

- O Blue opsin is restricted to the outer segments of blue cones in the affected retina.
- Red/green opsins are distributed along the entire plasma membrane of this cone type, from the tip of the outer segment to the synaptic base.
- O The cone IPM displayed a heterogeneous distribution.
- O The cone pedicles appeared larger than normal, both in the macula and the periphery.
- Rhodopsin staining was not different from the control eye.
- O The distribution of the studied markers is similar both in the macula and in the periphery of the affected retina.

# Abstract

Purgoace, RPE65 is an enzyme exclusively expressed in the retinal pigment epithelium (RPE) that converts trans retinol to the 11-cis form. Mutations in this gene are found in some recessive forms of Leber conspiral amarcisis. We evaluated the histopathology of a donor eye from a patient with a homozypous missense change Ala132Thr in the RPE65 gene. Methods: Autopoy evels were folkand from a 55 year did woman who died from metastatic breast cancer. The eyes were foxed in 4% paraformiadehyed and 0.5% glutraidehyed in phosphate buffer within 135 hours pointments. Small areas from the future parophery were processed for electron microscopy and indeed immunfluorescence, using monoconal antibodies to rhodopsin (mAb BSSN) and cone areastin (mAb 705). The control adultomizerotim thatish was analyzed. The affected donor and cone areastin (mAb 705). eye was compared to a matched normal eye. Results: The patient had night deficiency and decreased side vision since childhood. At age 51 she had

Beautigs: The patient had night deficiency and decreased side visions since childhood. At age 51 she had hand motions OD and 20200 OS, a certral siland of vision with far peripheral creacestral OU, and peripheral home spicule pigmentation OU. Cone ERGs were barely defectable. Histologic tindings revealed a highly disognarized relative with indistinct layers in each quadratic. The RFE layer displayed homeoing in the mount, but were mostly absent from the relinal periphery. Core synchron. Corees were beerved. Autoincorescent material was greatly reduced in the RFE in all areas studed. Conclusions: This patient with an RFE65 mutation showed an absence of rods and cores in the autoincorescent material was process for an abcence of rods and cores in the layotoreceptor user segment renewage process for an abcence period. But Conclusions: Deplotere-gath or using process for an abcenced period of them. Conter Grant from Supprocession the region RFP gibling Bindinges Hestgathology Caret. # Introduction

The retinal pigment epithelium-specific 65 kDa protein is expressed by the RPE and is involved in The retinal pignent epithelium-specific 65 k0a protein is expressed by the RPE and is involved in the conversion of altrans retinol to 11-ceristinal during hototransduction, which is then used in visual pignent regeneration in photoreceptor cells. There are two forms of this protein, a soluble form called RPE65, and a painthylatid, membrane-bound form known as mRPE65. Trapeted disruption of the mouse Rpe65 gene leads to absence of 11-cer retinal in the photoreceptor ouder segments together supporting the hypothesis that the RPE65 protein is essential for the isomerization of altrane reting takes (Redmond et al., 1996). These Redmond et al., 1997, Manuel edisases that throwle impaired distance from birth dury burget progress to bindness in the hird decide of II-(Qu et al., 1997, Marines et al., 1997, Morimus et al., 2007. 1998; Lorenz et al., 2000; Paunescu et al., 2005). This donor had a homozygous mutation Ala132Thr in this gene. She had a clinically affected brother who also showed this mutation homozygously and a clinically unaffected sister who is heterozygous for this mutation (Morimura, et al., 98). Unlike most

clinically unaffected sister who is heterozygous for this mutation (Morimura, et al., 98). Unlike most patients with RPESS mutations she rever, features of the tober early filters. Like many genetic diseases, this condition is presently incurable. Although the relnal dystrophese caused by defects in RPESS are severe, features of the disorder such as useful visual luricotin in childhood and photoreceptor-call death late in the disease process suggest that it may respond to pan-registreament therapy. Over 60 different pathogenic mutations of RPESS are known and these affect all 14 exons of the gene and its boundaines. Severity and age of onset of disease are related to the particular type of mutation and the residualistic affect (Resimond, 2003) unlike of photoreceptor markers in a donor eye from a female affected by an RPESS mutation. # Abstract

emenogelin I (SgI) and II (SgII) are the major structural protein components of semen Their function is not fully understood, but several activities have been ascribed to coagulum. Their function is not fully understood, but serveil activities have been ascribed to semenogein or semenogein-dervele petides, e.g. inhibition of sperm molity and capacitation, activation of sperm hyaluronicase and antibacterial properties. Recently, we reported the presence and localization of bits gli and sgli in the RPC, insult effect, local reflexion (shorted, photorespots, niem rudeer layer and gargition cell layer) and vitreous of human donors not diagnosed with any eye disease. In the present study, we further analyzed the expression of these proteins in the relinal cells of ADID.

eyes in vice. Methods: Coyo and paraffin sections of human retina were processed for both immunofluorescence and DAB reaction with an antibody that recognizes both forms of semenogelin proteins. The presence of both proteins was analysed in relian and PRE both Jayase. Basults: Both proteins were detected by western both in human RPE. However, the intensity of methods: Detection and the proteins were detected by western both in human RPE. However, the intensity of the tigs of the proteins were detected by western both in human RPE. However, the intensity of <u>Conclusions</u>: Semengein 1 and II are expressed in the normal human retina and in the retina of ADM door regist. The expression of semengeins in the ADM perior special subplicit bior than that observed in the normal retina. A recent report indicates that both Squ and Sgll bind zinc. # Introduction

Semenogelin I and II are secreted from the glandular epithelium of the seminal vesicles and the pithelium of the epididymis (Bjartell et I., 1996). Semenogelin I (Sql) is a non-glycosylated protein epithetium of the epidopmis (giparel et 1, 1996). Somenopelin (5g)) is a non-glycosylated protein with a molecular mass of SXDG Lilla et 1, 1989. Semenopelin (15g)) has a molecular mass of SXDA (Lilla and Lundwall, 1992). It has a potential stef for Ninited glycosylation and around half of the moleculer is sensing Jasama are glycosylated, yielding the molecular mass of therence of SXDa (Lilla and Lundw, 1965). Studies have indicated a role of semenopelin moleculer sensition is capacitation and molecular specific the molecular specific the sensitivity of spem (Host).

al., 2001). Recently, seemagelin proteins expression was characterized in non-genital itsues like trachea, bronchi, skeetali muscle cella, and cella in the certral nervous system (Lundvall et al., 2002), augebrarge and out such tooth characterise to the protein section of the land of selection augebrarge and the statistical control of the protein section of the land of selection donors (Boniha et al., 2000). These findings have not been subtantiated by independent studies and it is therefore still unclear whitch the semenogilin proteins have any function beads there in the statistic studies and studies and a 2,2000, as recompositive demonstration, control augebra that thereoligi minimum and studies and studies and a 2,2000, as recompositive demonstration, cold suggest that stremogelin molecular and SqL (Lonson et al., 2000).

and Sgil Conston et al. 2005, as recently demonstrated, could suggest that semengalin metcules metcal. Each set of the semengality of the set of the semengality of the set of sed AMD

Samenogalin protein localization is remarkably decreased in the ratinss of AMD denors. 5µm parallin sections of human donors previously diagnosed with AMD (B, C, E, F) and control eyes (A, D) were probed with semenogalin 1 antibody in 5% both for that RT, wated, and incolated with which in PSP to 50 min, the developed with DAB for 2 multisk. The control is the second of the second s

# Summary

Semenogelin molecules are expressed in the eye, in the vitreou and in several cell types of the retina.

**ED** 

Foundation Fighting Blindness

- In control samples semenogelin molecules are expressed by the RPE, the photoreceptors (both cones and rods), the ganglion cells and cells in the inner nuclear/outer plexiform laver
- In AMD tissue semenogelin molecules distribution in retinal sections is greatly decreased. In some donors a weak localization in the tips of the photoreceptor outer segments was still observed, but in the majority of the AMD samples photoreceptor and RPE localization of semenogelin undecules was completely lost.
  - Presence of semenogelin I is significantly decreased in retinal lysates from AMD donors.
  - Presence of semenogelin I is significantly decreased lysates from AMD donors.
